

Question: 1

- Photosynthesis is the process by which green plants make their own food. Plants use sunlight, carbon dioxide from the air, and water from the soil to produce glucose. This process happens in chlorophyll chloroplasts where chlorophyll absorbs light energy.

Question : 2

- Mitosis and meiosis are both types of cell division, but they are different. Mitosis produces two identical diploid daughter cells, it is used for growth, repair & replacement of cells. Meiosis produces four genetically different haploid cells.

Question : 3

- Cell division is important because it helps organisms grow and repair damaged tissues. It also replaces old or dead cells. In unicellular organisms, cell division is a method of reproduction.
